

# Bayesian calibration of numerical models using Gaussian processes

François Bachoc

CEA-Saclay, DEN, DM2S, SFME, LGLS, F-91191 Gif-sur-Yvette, France.  
Laboratoire de Probabilités et Modèles Aléatoires, Université Paris VII

## Context

- Phd started in October 2010 in partnership between CEA and Paris VII university.
- CEA supervisor: Jean-Marc Martinez.
- Paris VII supervisor: Josselin Garnier.

## Subject

- Probabilistic modelling of the error between a numerical code (or numerical model) and the physical system.
- Goals: To calibrate the numerical code and to improve its predictions.

- 1 Deterministic calibration
- 2 Statistical model
- 3 Calibration and prediction
- 4 Model selection
- 5 Application to the isotherm friction model
- 6 Conclusion

# Numerical code and reality

A numerical code, or parametric numerical model, is represented by a function  $f$ :

$$\begin{aligned} f &: \mathbb{R}^d \times \mathbb{R}^m \rightarrow \mathbb{R} \\ & (x, \beta) \rightarrow f(x, \beta) \end{aligned}$$

The physical phenomenon is represented by a function  $Y_{real}$ .

$$\begin{aligned} Y_{real} &: \mathbb{R}^d \rightarrow \mathbb{R} \\ & x \rightarrow Y_{real}(x) \end{aligned}$$

- The inputs  $x$  are the experimental conditions.
- The inputs  $\beta$  are the calibration parameters of the numerical code.
- The output  $f(x, \beta) - Y_{real}(x)$  is a quantity of interest.

A numerical code modelizes (gives an approximation of) a physical phenomenon.

Conclusion

We dispose of a set of experimental results:  $x_1, Y_{obs}(x_1), \dots, x_n, Y_{obs}(x_n)$ .

## Least Square calibration:

- Compute:

$$\hat{\beta}_{LS} \in \arg \min_{\beta} \sum_{i=1}^n (f(x_i, \beta) - Y_{obs}(x_i))^2$$

- For new experimental condition  $x_{new}$  we predict the quantity of interest by:  
 $f(x_{new}, \hat{\beta}_{LS})$ .

# Least Square calibration: Case of insufficiency

- In general:

$$\sum_{i=1}^n \left( f(x_i, \hat{\beta}_{LS}) - Y_{obs}(x_i) \right)^2 \neq 0$$

- First justification:  $Y_{obs}(x_i) = Y_{real}(x_i) + \epsilon$ ,  $\epsilon \sim \mathcal{N}(0, \sigma_{mes}^2)$ .
- Problem when  $\sigma_{mes}$  (or an upper-bound) is known and when the errors  $f(x_i, \hat{\beta}_{LS}) - Y_{obs}(x_i)$  are still too large. (Statistical tests available to detect).
- In these cases: a model error needs to be taken into account.

6 Conclusion

## Random processes

A real random process  $Z$  on  $\mathbb{R}^d$  is an application  $Z: \Omega \times \mathbb{R}^d \rightarrow \mathbb{R}$ , with  $\Omega$  a probability space, so that for all fixed  $x \in \mathbb{R}^d$ ,  $\omega \rightarrow Z(\omega, x)$  is a random variable.

- Notion of "random function".

## Finite dimensional distributions of a random process

Let us consider  $n$  points of  $\mathbb{R}^d$ :  $x_1, \dots, x_n$ . By definition, the vector  $(Z(x_1), \dots, Z(x_n))$  is a random vector of  $\mathbb{R}^n$ . Its distribution is said to be a finite dimensional distribution of  $Z$ . The finite dimensional distributions of  $Z$  are the set of these distributions with  $n$  et  $x_1, \dots, x_n$  varying.

- In the sequel, we only consider finite dimensional distributions: Classical probabilities on  $\mathbb{R}^n$ .

## Processus gaussien

A real random process  $Z$  on  $\mathbb{R}^d$  is Gaussian when its finite dimensional distributions are Gaussian.

- In the sequel, we only consider Gaussian processes.

## Mean and covariance functions

Mean function  $M: x \rightarrow M(x) = \mathbb{E}(Z(x))$

Covariance function  $C: (x_1, x_2) \rightarrow C(x_1, x_2) = \text{cov}(Z(x_1), Z(x_2))$

- Finite dimensional distributions of a Gaussian process are characterized by its mean and covariance functions.

## Stationary Gaussian process

A Gaussian process  $Z$  is said to be stationary when its mean function  $M$  is constant and when  $\forall x_1 x_2: C(x_1, x_2) = C(x_1 - x_2)$ .

# Gaussian processes (3/3)

## Examples of covariance functions

Nugget model  $C(x - y) = \sigma^2 \delta_{x-y}$

Gaussian covariance model  $C(x - y) = \sigma^2 \exp\left(-\frac{\|x-y\|^2}{l_c^2}\right)$

## Examples of realizations with Gaussian covariance function

Figure: Left:  $\sigma = 0.2$ ,  $l_c = 0.01$ . Right:  $\sigma = 0.2$ ,  $l_c = 0.05$

**Statistical modelling:** The physical phenomenon is one realization among a set of possible realizations. It is modeled as a realization of a random process.

## Equation of the statistical model

$$Y_{real}(\omega, x) = f(x, \beta(\omega)) + Z(\omega, x)$$

- Equation that holds for a specific parameters vector  $\beta$ . Called "the" parameter of the numerical code.
  - No prior information case:  $\beta$  constant and unknown.
  - Prior information case (Bayesian case):  $\beta \sim \mathcal{N}(\beta_{prior}, Q_{prior})$
- $Z$  is (a priori) a **centered, stationary, Gaussian** process. We denote by  $C_{mod}$  the covariance function of  $Z$ .

## Why a stationary Gaussian process?

- Gaussian variables: most commonly used to represent errors. Gaussian property conserved by conditional expectations and linear transforms.
- Stationarity: restrict the number of possible Gaussian processes (statistical bias-variance trade-off). In statistical inference: replace sample repetition (iid case) by spatial repetition.

# Goals associated to the modelling

Conclusion

## Kinds of work to do:

- 1 The covariance function of the model error is known: **Calibration** and **Prediction**.
- 2 A covariance function is proposed: **Model test**.
- 3 The covariance function is unknown: **Model selection**.

## Classical outline of studies using the modelling

- Step 1: Estimation of the hyper-parameters of the covariance function.
- Step 2: Plug-in of the estimated hyper-parameters to perform calibration and prediction.

Linearization of the numerical model around the reference parameter:

$$\forall x : f(x, \beta) = \sum_{i=1}^m h_i(x) \beta_i$$

## Observations

We observe the physical phenomenon  $Y_{real}(x)$  for  $n$  inputs  $x_1, \dots, x_n$ . Define:

- $n \times m$  matrix of partial derivatives of the numerical model:  $H$ .
- Random vector of observations:  $y_{obs}$ .
- Random vector of measure error:  $\epsilon$ .
- Random vector of model errors:  $z$ .
- Covariance matrix of  $z$ :  $R_{mod}$ .

# Matrix equation of the statistical model

Bayesian  
calibration  
of  
numerical  
models  
using  
Gaussian  
processes

The statistical model becomes, for the inputs  $x_1, \dots, x_n$ :

$$y_{obs} = H\beta + z + \epsilon$$

## Covariance matrix of $z + \epsilon$

$$R := \text{cov}(z + \epsilon) = R_{mod} + K$$

With  $K := \text{cov}(\epsilon)$ .  $K$  is diagonal. Most classical case:  $K = \sigma_{mes}^2 I$ .

- No prior information case
  - When  $R = \sigma^2 I_n$ : Classical linear regression model.
- Prior information case

$$y_{obs} \sim \mathcal{N}(H\beta_{prior}, R + HQ_{prior}H^T)$$

- Main interest of the correlation: Efficient prediction of the phenomenon when it does not have the same shape as the numerical code.

model

Conclusion

- 1 Deterministic calibration
- 2 Statistical model
- 3 Calibration and prediction**
- 4 Model selection
- 5 Application to the isotherm friction model
- 6 Conclusion

Calibration problem = Statistical estimation problem

## Estimation of $\beta$

- An estimator of  $\beta$  is a function  $\hat{\beta}: \mathbb{R}^n \rightarrow \mathbb{R}^m$ .
- $\hat{\beta}(y_{obs})$  is the estimation of  $\beta$  according to the vector of observations  $y_{obs}$ .
- Quality measure of an estimator: **Mean square error**:  $\mathbb{E}_{y_{obs}, \beta} [||\beta - \hat{\beta}(y_{obs})||^2]$ .

## No prior information case

The estimator  $\hat{\beta}$  of  $\beta$ , linear with respect to the vector of observations  $y_{obs}$ , unbiased, which minimizes the mean square error is:

$$\hat{\beta} = (H^T R^{-1} H)^{-1} H^T R^{-1} y_{obs}$$

- If  $y_{obs} = H\beta$ ,  $\hat{\beta}(y_{obs}) = \beta$

## Prior information case

In the prior information case, the conditional law of  $\beta$ , according to the observations  $y_{obs}$  is Gaussian with mean  $\beta_{post}$ , where

$$\beta_{post} = \beta_{prior} + (Q_{prior}^{-1} + H^T R^{-1} H)^{-1} H^T R^{-1} (y_{obs} - H\beta_{prior}).$$

- Best predictor according to the mean square error.
- When  $Q_{prior}^{-1} \rightarrow 0$  (Uninformative prior) we find the prediction of the no prior information case, even if  $\beta_{prior} \neq 0$ .

Goal: to complete the prediction of  $f(x_0, \hat{\beta})$  at a new point  $x_0$ .

## Notations

- Physical phenomenon at  $x_0$ :  $y_0 := Y_{real}(x_0)$ .
- (pseudo) new observation at  $x_0$ :  $y_{obs,0}$ .
- Column vector of partial derivatives of the code:  $h_0$ .
- Random variable of the model error:  $z_0$ .
- Random variable of the measure error:  $\epsilon_0$ .
- Column covariance vector  $r_0$ :  $r_{0,i} := \text{cov}((z + \epsilon)_i, z_0 + \epsilon_0)$ .

## Prediction of $y_0$

- A predictor of  $y_0$  is a function  $\langle y_0 \rangle: \mathbb{R}^n \rightarrow \mathbb{R}$ .
- $\langle y_0 \rangle(y_{obs})$  is the prediction of  $y_0$  according to the vector of observations  $y_{obs}$ .
- Quality measure of a predictor: Mean square error:  $\mathbb{E}_{y_{obs}, y_0} [ |y_0 - \langle y_0 \rangle(y_{obs})|^2 ]$ .

Application  
to the  
isotherm  
friction  
model

Conclusion

## Prediction

The unbiased predictor of  $y_{obs,0}$  at  $x_0$ , linear with respect to the vector of observations  $y_{obs}$ , which minimizes the mean square error (the BLUP) is:

$$\langle y_{obs,0} \rangle = (h_0)^T \hat{\beta} + (r_0)^T R^{-1} (y_{obs} - H \hat{\beta})$$

with  $\hat{\beta}$  the no prior information case estimator of  $\beta$ .

- We do not have access to the best predictor, because its expression makes use of the unknown parameter  $\beta$ .
- The prediction expression is decomposed into a calibration term and a Gaussian inference term of the model error.

## Predictive variance

The mean square error of the BLUP is:

$$\hat{\sigma}_{x_0}^2 = \mathbb{E}((z_0 + \epsilon_0)^2) - \begin{pmatrix} h_0 \\ r_0 \end{pmatrix}^t \begin{pmatrix} 0 & H^t \\ H & R \end{pmatrix}^{-1} \begin{pmatrix} h_0 \\ r_0 \end{pmatrix}$$

Confidence intervals available

# Prediction (3/4): Prior information case

## Prediction

The conditional law of  $y_{obs,0}$  according to the observations  $y_{obs}$  is Gaussian with mean  $\langle y_{obs,0} \rangle$ , with:

$$\langle y_{obs,0} \rangle = (h_0)^T \beta_{post} + (r_0)^T R^{-1} (y_{obs} - H \beta_{post})$$

- Best predictor.

## Predictive variance

Conditionally to  $y_{obs}$  the variance of  $y_{obs,0}$  is :

$$\hat{\sigma}_{x_0}^2 = \mathbb{E}((z_0 + \epsilon_0)^2) - \begin{pmatrix} h_0 \\ r_0 \end{pmatrix}^t \begin{pmatrix} -Q_{prior}^{-1} & H^t \\ H & R \end{pmatrix}^{-1} \begin{pmatrix} h_0 \\ r_0 \end{pmatrix}$$

- When  $Q_{prior}^{-1} \rightarrow 0$  (uninformative prior) we find the no prior information case.

# Prediction (4/4): from $y_{obs,0}$ to $y_0$

## No prior information case

The BLUP of the observation equals the BLUP of the physical phenomenon:

$$\forall \lambda \in \mathbb{R}^n : \mathbb{E} \left( (\lambda^t y_{obs} - y_{obs,0})^2 \right) = \mathbb{E} \left( (\lambda^t y_{obs} - y_0)^2 \right) + \mathbb{E} \left( (\epsilon_0)^2 \right)$$

## Prior information case

The conditional mean are the same and the conditional variance are the same up to the measure error:

- $\mathbb{E}(y_0 | y_{obs}) = \mathbb{E}(y_{obs,0} | y_{obs})$
- $\text{var}(y_{obs,0} | y_{obs}) = \text{var}(y_0 | y_{obs}) + \mathbb{E} \left( (\epsilon_0)^2 \right)$

→ In both cases, we keep the same prediction, and remove  $\mathbb{E} \left( (\epsilon_0)^2 \right)$  to the predictive variance.

# Illustration of calibration (1/3)

- Observation of the physical phenomenon:  $Y_{obs}(x) = x^2 + \epsilon$ .  
 $\epsilon \sim \mathcal{N}(0, \sigma_{mes}^2 = 0.1^2)$
- Numerical code:  $f(x, \beta) = \beta_0 + \beta_1 x$ .
- Model error as a realization of a Gaussian process with covariance function:  
 $C_{mod}(x - y) = \sigma^2 \exp\left(-\frac{|x-y|^2}{l_c^2}\right)$ .  $\sigma = 0.3$ ,  $l_c = 0.5$  (known).
- Bayesian case with :

$$\beta_{prior} = \begin{pmatrix} 0.2 \\ 1 \end{pmatrix}, Q_{prior} = \begin{pmatrix} 0.09 & 0 \\ 0 & 0.09 \end{pmatrix}$$

- Observations:  $x_1 = 0.2$ ,  $x_2 = 0.4$ ,  $x_3 = 0.6$  and  $x_4 = 0.8$ .

Conclusion

- Observation of the physical phenomenon:  $Y_{obs}(x) = -\sin(\frac{\pi x}{2}) + \epsilon$ .  
 $\epsilon \sim \mathcal{N}(0, \sigma_{mes}^2 = 0.1^2)$
- Numerical code:  $f(x, \beta) = \beta_0 + \beta_1 x + \beta_2 x^2 + \beta_3 x^3$ .
- Model error as a realization of a Gaussian process with covariance function:  
 $C_{mod}(x - y) = \sigma^2 \exp\left(-\frac{|x-y|^2}{l_c^2}\right)$ .  $\sigma = 0.3$ ,  $l_c = 0.5$  (known).
- No prior information case.
- 6 observations regularly sampled between  $-0.8$  and  $1.7$ .

## Illustration of prediction (2/3) (unnoised case)

- The use of the model error improves the prediction given by the numerical code.

# Illustration of prediction (3/3) (noised case)

- The measure error deteriorates the quality of the predictions.
- The confidence intervals are however still reliable.

- 1 Deterministic calibration
- 2 Statistical model
- 3 Calibration and prediction
- 4 Model selection**
- 5 Application to the isotherm friction model
- 6 Conclusion

- The calibration and prediction methods presented above give good results because we used a reasonable covariance function.
- The model selection is a statistical parameter estimation problem.

In our case, the covariance function of the measure error process  $\epsilon$  is known for physical expertise. We want to take  $C_{mod}$  in a parametric set:

$$\left\{ \sigma^2 C_{mod,\theta} \right\}$$

with  $C_{mod,\theta}$  a correlation function.

Hence, with variance matrix  $R_{\sigma,\theta} = \sigma^2 R_{mod,\theta} + K$ , we have  $(z + \epsilon) \sim \mathcal{N}(0, R_{\sigma,\theta})$  and we want to estimate  $\sigma$  and  $\theta$ .

We present 2 methods for model selection: **Restricted Maximum Likelihood** and **Leave One Out**.

# Restricted Maximum Likelihood

Bayesian  
calibration  
of  
numerical  
models  
using  
Gaussian  
processes

François  
Bachoc

Deterministic  
calibration

Statistical  
model

Calibration  
and  
prediction

Model  
selection

Application  
to the  
isotherm  
friction  
model

Conclusion

Principle: Estimate  $\sigma$  and  $\theta$  independently of  $\beta$  (hence, same method with or without prior information).

Let  $C$  a  $(n - m \times n)$  matrix of maximal rank such that  $CH = 0$ . Then we have:

$$w := Cy_{obs} \sim \mathcal{N}(0, CR_{\sigma, \theta}C')$$

We do maximum likelihood on the vector  $w$ .

The likelihood writes itself:

$$\ell_{\sigma, \theta}(w) \propto \frac{1}{\det(CR_{\sigma, \theta}C')^{\frac{1}{2}}} \exp\left(-\frac{1}{2}w^t(CR_{\sigma, \theta}C')^{-1}w\right)$$

We maximize it:

$$\hat{\sigma}, \hat{\theta} \in \arg \max_{\sigma, \theta} \ell_{\sigma, \theta}(w).$$

Hence we estimate  $\sigma$  and  $\theta$  to make the vector  $w$  the most probable.

# Leave One Out (1/4)

We have seen that the prediction procedure (Bayesian or non-Bayesian framework) leads to a simple stochastic metamodel:  $x_0 \rightarrow \mathcal{N}(\langle y_{obs,0} \rangle, \hat{\sigma}_{x_0}^2)$ . This metamodel depends on  $\sigma$  and  $\theta$ .

- It is built according to the observations ( $\approx$  learning set).

## Leave One Out

- Given a vector of hyper-parameters  $(\sigma, \theta)$ .
- For  $i$  from 1 to  $n$  we learn  $x_0 \rightarrow \mathcal{N}(\langle y_{obs,0} \rangle, \hat{\sigma}_{x_0}^2)$  with the reduced observations vector  $\{(x_1, y_{obs,1}), \dots, (x_{i-1}, y_{obs,i-1}), (x_{i+1}, y_{obs,i+1}), \dots, (x_n, y_{obs,n})\}$
- we compute the **LOO errors** by:

$$\epsilon_{LOO,i}(\sigma, \theta) = y_{obs,i} - \langle y_{obs,i} \rangle(y_{obs,-i}).$$

- we compute the **LOO predictive variance** by:

$$\hat{\sigma}_{LOO,i}^2(\sigma, \theta) = \hat{\sigma}_{x_i}^2(y_{obs,-i})$$

General utility of the Leave One Out:

- See how large the errors are.
- Check that the predictive variance are of the right size.

# Leave One Out (2/4): closed form formulas

## No prior information case

With:

$$Q^{-}(\sigma, \theta) = \left( R_{\sigma, \theta}^{-1} - R_{\sigma, \theta}^{-1} H (H^T R_{\sigma, \theta}^{-1} H)^{-1} H^T R_{\sigma, \theta}^{-1} \right)$$

We have:

$$\epsilon_{LOO}(\sigma, \theta) = (\text{diag}(Q^{-}))^{-1} Q^{-} y_{obs} \quad \text{and} \quad \hat{\sigma}_{LOO, i}^2(\sigma, \theta) = \frac{1}{(Q^{-})_{i, i}}$$

## Prior information case

With:

$$Q = R_{\sigma, \theta} + H Q_{prior} H^t$$

We have:

$$\epsilon_{LOO}(\sigma, \theta) = (\text{diag}(Q^{-1}))^{-1} Q^{-1} y_{obs} \quad \text{and} \quad \hat{\sigma}_{LOO, i}^2(\sigma, \theta) = \frac{1}{(Q^{-1})_{i, i}}$$

# Leave One Out (3/4): closed form formulas

isotherm  
friction  
model

Conclusion

General principle, optimize a quality criterion based on  $\epsilon_{LOO}(\sigma, \theta)$  and the  $\hat{\sigma}_{LOO,i}^2$ . For instance:

- Minimize norm of LOO errors.
- Set number of valid LOO p-confidence intervals close to p.
- Set  $\frac{1}{n} \sum_{i=1}^n \frac{\epsilon_{LOO,i}^2(\sigma, \theta)}{\hat{\sigma}_{LOO,i}^2(\sigma, \theta)}$  close to 1

When the covariance matrix  $K$  of the measure error is null and no prior information case, we have  $R_{\sigma, \theta} = \sigma^2 R_{mod, \theta}$ , hence:

- $\epsilon_{LOO}(\sigma, \theta)$  independent of  $\sigma$
- $\hat{\sigma}_{LOO}^2(\sigma, \theta) = \sigma^2 \hat{\sigma}_{LOO}^2(\theta)$

Hence a classical method is:

$$\hat{\theta} \in \arg \min_{\theta} \|\epsilon_{LOO}(\theta)\|^2 \quad \text{and} \quad \hat{\sigma}^2 = \frac{1}{n} \sum_{i=1}^n \frac{\epsilon_{LOO,i}^2(\hat{\theta})}{\hat{\sigma}_{LOO,i}^2(\hat{\theta})}$$

When  $K \neq 0$  or prior information case: no classical method.

Conclusion

The experiment consists in the measure of a pressure drop between the two ends of a cylinder crossed by pressurized water and possibly heat. (Representation of the heart of a nuclear reactor).

Quantity of interest: The part of the pressure drop due to friction:  $\Delta P_{fro}$

Experimental conditions we consider:

- Hydraulic diameter  $D_h$
- Friction height  $H_f$
- Density  $\rho$
- Viscosity  $\mu$
- Flow rate  $G$
- Reynolds coefficient  $R_e$

Model in the isotherm turbulent physical domain is parameterized by  $a_t, b_t$ :

$$\text{with } R_e = \frac{GD_h}{\mu}, \quad \Delta P_{fro}^{mod} = \frac{H_f G^2}{2\rho D_h} \times a_t R_e^{-b_t}$$

Previous studies of calibration:  $a_t = 0.22, b_t = 0.21$

We dispose of 85 experimental results in this domain. Hence  $n = 85, m = 2$ .

# Need for a model error?

## Statistical test

Let  $C$  a  $(83 \times 85)$  matrix of full rank such that  $CH = 0$ . Recall  $K$  is the covariance matrix of the measure error process and assume there is no model error. Then

$$t_{test} := (C y_{obs})^t (CKC^t)^{-1} C y_{obs} \sim \chi^2(83).$$

## Measure error on experimental conditions

We have nominal measure error variance on 3 experimental conditions:

- $\sigma_{nom}(H_f)$
- $\sigma_{nom}(D_h)$
- $\sigma_{nom}(G)$

They can be formally taken into account in the measure error covariance matrix  $K$ . The statistical test is still correct.

Test result:

$\sigma_{mes}(Pa)$	$\alpha(H_f) \times \sigma_{nom}(H_f)$	$\alpha(D_h) \times \sigma_{nom}(D_h)$	$\alpha(G) \times \sigma_{nom}(G)$	$t_{test}$
100.	$0 \times \sigma_{nom}(H_f)$	$0 \times \sigma_{nom}(D_h)$	$0 \times \sigma_{nom}(G)$	4334.1393
100.	$1 \times \sigma_{nom}(H_f)$	$1 \times \sigma_{nom}(D_h)$	$1 \times \sigma_{nom}(G)$	489.22775
200.	$2 \times \sigma_{nom}(H_f)$	$2 \times \sigma_{nom}(D_h)$	$2 \times \sigma_{nom}(G)$	122.30694

→ Need for a model error ( $q_{0.95}(\chi^2(83)) \approx 105$ ).

Conclusion

We want to compare the quality of prediction of the LS method and the GP modelling method.

Idea: They both are **metamodels** of the physical phenomenon.

## metamodel

Let  $f: \mathcal{X} \rightarrow \mathbb{R}$ . A metamodel is a function  $\hat{f}_{\mathcal{X}_n, \mathcal{Y}_n}$ , built from a procedure  $\hat{f}$ :

$$\hat{f}: [\mathcal{X}_n, \mathcal{Y}_n] = [x_1, \dots, x_n, y_1, \dots, y_n] \longrightarrow \hat{f}_{\mathcal{X}_n, \mathcal{Y}_n}.$$

With  $\hat{f}_{\mathcal{X}_n, \mathcal{Y}_n}: \mathcal{X} \rightarrow \mathbb{R}$  an approximation of  $f$ .

## Evaluation of a metamodel

Quality criterion:

$$C = \frac{1}{\text{Vol}(\mathcal{X})} \int_{\mathcal{X}} \left( f(x) - \hat{f}_{\mathcal{X}_n, \mathcal{Y}_n}(x) \right)^2 dx,$$

Ideal case: estimation of this criterion on a **new** test sample  $\mathcal{X}_{test}, \mathcal{Y}_{test}$ :

$$C \approx \frac{1}{n_{test}} \sum_{i=1}^{n_{test}} \left( f(x_{test,i}) - \hat{f}_{\mathcal{X}_n, \mathcal{Y}_n}(x_{test,i}) \right)^2.$$

# Cross Validation for comparison with Least Square (2/2)

## Evaluation of a metamodel

More realistic case: split the learning data:  $\mathcal{X}_n = (\mathcal{X}_{app}, \mathcal{X}_{test})$  ( $n = n_{app} + n_{test}$ ):

$$C \approx \frac{1}{n_{test}} \sum_{i=1}^{n_{test}} \left( f(x_{test,i}) - \hat{f}_{\mathcal{X}_{app}, \mathcal{Y}_{app}}(x_{test,i}) \right)^2.$$

**K Fold Cross validation** is an iteration of this principle. Divide the data:  $\mathcal{X}_n = (\mathcal{X}_1, \mathcal{X}_2, \dots, \mathcal{X}_K)$ , and use:

$$C \approx \frac{1}{n} \sum_{k=1}^K \sum_{x_i \in \mathcal{X}_k} \left( f(x_i) - \hat{f}_{\mathcal{X}_{-k}, \mathcal{Y}_{-k}}(x_i) \right)^2$$

Hence, each  $f(x_i)$  is predicted one time, with a learning sample that does not contain it.

In our case we will take  $K = 10$ , and:

$$\begin{aligned} \mathcal{X}_1 &= (x_1, x_{11}, x_{21}, x_{31}, x_{41}, x_{51}, x_{61}, x_{71}, x_{81}) \\ &\dots \end{aligned}$$

As experiments are grouped, we have heterogeneity in each test sample, and reproducibility of the Cross validation.

We trust that  $\Delta P_{fro} \propto H_f$ . Hence we do both LS and GP on the pseudo-measure  $\frac{\Delta P_{fro}}{H_f}$ .  
For evaluation of predictions we go back to the  $\Delta P_{fro}$  quantity.

## Least Square

- Prediction formulas with an iid model error and prior information case.
- $\beta_{prior} = (0.22, 0.21)^t$ ,  $Q_{prior}$  diagonal with standard-deviation at 50% of  $\beta_{prior}$ .
- Model error variance estimated by REML.
- We are similar to LS in prediction because the prediction only uses the calibrated code.
- We have predictive variance and hence confidence intervals.

## Gaussian Process Modelling

- Choice of the covariance function:  
Use of the Matern stationary covariance function:  
 $C_{mod}(x) = \sigma^2 \prod_{i=1}^d \text{Matern}(2\sqrt{\nu} \frac{x_i}{l_{c,i}})$  with:

$$\text{Matern}(x) = \frac{1}{\Gamma(\nu)2^{\nu-1}} x^\nu K_\nu(x)$$

with  $K_\nu$  the modified Bessel function of order  $\nu$ . Hyper-parameters are:  $\sigma$  (Variance),  $l_{c,1}, \dots, l_{c,d}$  (correlation lengths) and  $\nu$  (regularity). We enforce  $\nu = \frac{3}{2}$ .

- Choice of the experimental conditions:
  - Interest of division by  $H_f$ : simplification of the correlation function  $\rightarrow$  less hyper-parameters to estimate. (very few values for  $H_f$ )
  - $\rho$  and  $\mu$  are physically linked, we merge them into a pseudo-experimental condition  $X_{\rho,\mu}$ .
  - 4 hyper-parameters to estimate:  $\sigma, l_G, l_{D_h}, l_{\rho,\mu}$ .
- Estimation:
  - REML estimation.
  - We linearly transform all experimental condition to put them in  $[0, 1]$ .

With the Cross Validation we use, each experiment is predicted one time. Hence we dispose of:

- The vector of predictions  $\Delta \hat{P}_{fro}^{exp}$  of size 85.
- The vector of predictive variance  $\sigma_{pred}^2$  of size 85.

2 quantitative criteria:

- RMSE:  $\sqrt{\frac{1}{85} \sum_{i=1}^{85} (\Delta P_{fro}^{exp} - \Delta \hat{P}_{fro}^{exp})^2}$
- Confidence Intervals:  $\frac{1}{85} \text{card} \left\{ i | 1 \leq i \leq 85, |\Delta \hat{P}_{fro,i}^{exp} - \Delta P_{fro,i}^{exp}| \leq 1.64 \sigma_{pred,i} \right\}$   
(should be around 0.9)

We do 2 different cases:

- **Case 1** We do not take measure error on  $H_f$ ,  $G$  and  $D_h$  into account. We enforce  $\sigma_{mes} = 200^2$ . Hence  $K = \sigma_{mes}^2 I_n$ .
- **Case 2** We take the measure error on  $H_f$ ,  $G$  and  $D_h$  into account (nominal values of the statistical test part). We enforce  $\sigma_{mes}^2 = 100^2$ .

Conclusion

## Conclusion

- We can improve the prediction capability of the numerical model by completing it with a statistical model based on the observations.
- In the application case: Cross Validation estimation of the 'performances' (for both LS and GP) are accurate when we want to predict at an **experimented** geometry.
- The hyper-parameter estimation step is important.
- Computationally expensive when the number of experiments is large (But there exists state of the art methods).

## Prospects

- Hyper-parameter estimation by Leave One Out or Cross Validation.
- Application on the Friction model in more general physical domains → more physical models to calibrate with more experiments
