# Families of codes exceeding the Varshamov-Gilbert bound. Marc PERRET 

- Equipe CNRS "Arithmétique et Théorie de l'Information" -- CIRM - Luminy - Case 916-13288 Marseille Cedex 9.

Résumé : Le nombre $\mathrm{A}(\mathrm{q})$ est la limite supérieure du nombre maximum de points d'une courbe algébrique définie sur le corps fini à q éléments, divisé par le genre. J.-P. Serre a montré que $\mathrm{A}(\mathrm{q}) \geq \mathrm{c} \operatorname{logq}$, où c est une constante positive non nulle. Sa méthode, liée à l'existence de tours infinies de corps de classes de Hilbert, peut donner de meilleurs résultats ; on donne ici de nouvelles minorations de $\mathrm{A}(\mathrm{q})$ pour certaines valeurs de q , après avoir montré comment on peut en déduire de nouvelles valeurs de q pour lesquelles il existe des familles de codes sur $\mathbf{F}_{\mathrm{q}}$ dépassant la borne de Varshamov-Gilbert.

#### Abstract

The number $\mathrm{A}(\mathrm{q})$ is the superior limit of the maximum number of points of an algebraic curve defined over the finite field with $q$ elements, divided by the genus. It has been shown by J.-P. Serre that $\mathrm{A}(\mathrm{q}) \geq \mathrm{c} \operatorname{logq}$, where c is a positive constant. His method, based on the existence of infinite towers of Hilbert-class fields, can give better results ; we give here some new lower bounds for $\mathrm{A}(\mathrm{q})$ for certain values of q , and we deduce from these some new values of $q$ for which there exists families of codes defined over $\mathbf{F}_{\mathrm{q}}$, exceeding the Varshamov-Gilbert bound.

## I. The domain of codes.

Let q be a power of a prime number, and $\mathrm{C}_{\mathrm{q}}$ be the set of codes defined over $\mathrm{F}_{\mathrm{q}}$. To each code C of $\mathrm{C}_{\mathrm{q}}$, we can associate its three parameters $[\mathrm{n}, \mathrm{k}, \mathrm{d}]_{\mathrm{q}}$ : lenght, dimension and minimum weight. Let us note $\delta(\mathrm{c})=\mathrm{d} / \mathrm{n}$ the relative distance of C , and $\mathrm{R}(\mathrm{c})=\mathrm{k} / \mathrm{n}$ its transmission rate. We put $\mathrm{V}_{\mathrm{q}}=\left\{(\delta(\mathrm{c}), \mathrm{R}(\mathrm{c})) ; \mathrm{C} \in \mathrm{C}_{\mathrm{q}}\right\}$, and we denote by $\mathrm{U}_{\mathrm{q}}$ the set of limit points of $\mathrm{V}_{\mathrm{q}} . \mathrm{U}_{\mathrm{q}}$ is called the domain of codes over $\mathbf{F}_{\mathrm{q}}$. The question is to study this set. For more details, see [3].The first result is the following :

Theorem 1. (Manin). For $0 \leq \delta \leq 1$, let $\mathrm{a}_{\mathrm{q}}(\delta)=\operatorname{Sup}\left\{R ;(\delta, R) \in \mathrm{U}_{\mathrm{q}}\right\}$.

1) $a_{q}$ is a continuous, decreasing function on [ 0,1$]$, vanishing on $\left[\frac{q}{q-1}, 1\right]$.
2) $\mathrm{U}_{\mathrm{q}}=\left\{(\delta, \mathrm{R}) ; 0 \leq \delta \leq \frac{\mathrm{q}}{\mathrm{q}-1} ; 0 \leq \mathrm{R} \leq \mathrm{a}_{\mathrm{q}}(\delta)\right\}$.
3) $\mathrm{a}_{\mathrm{q}}(0)=1 ; \mathrm{a}_{\mathrm{q}}(\delta) \leq \operatorname{Max}\left(1-\frac{\mathrm{q}}{\mathrm{q}-1} \delta ; 0\right)$.

For a proof of this theorem, see [2]. The majoration 3) is called the Plotkin majoration, and is a trivial consequence of the bound of the same name. We can, in an other direction, give a very important lower bound for $\mathrm{a}_{\mathrm{q}}$ :

Theorem 2. (Varshamov-Gilbert). For $0 \leq \delta \leq 1$, let $\alpha_{q}(\delta)=1-H_{q}$ ( $\delta$ ), with

$$
\mathrm{H}_{\mathrm{q}}(\delta)=\delta \log _{\mathrm{q}}(\mathrm{q}-1)-\delta \log _{\mathrm{q}} \delta^{\mathrm{q}}-(1-\delta) \log _{\mathrm{q}}(1-\delta)
$$

the entropy function. Then, for $0 \leq \delta \leq 1, \alpha_{q}(\delta) \leq \mathrm{a}_{\mathrm{q}}(\delta)$.

More than twenty five years of research made it plausible to think that this boundary is the best possible. Throughout this lecture, we say that a family of code is excellent if its parameters have a limit point lying above the Varshamov-Gilbert bound. The purpose of this lecture is to prove the existence of excellent families of codes for certain values of $q$.

## II. Goppa codes.

These codes, also called geometric codes, are constructed from algebraic curves defined over $\mathbf{F}_{\mathrm{q}}$, e.g. sets defined by a finite number of polynomial equations with coefficients in $\mathbf{F}_{\mathrm{q}}$. To each irreductible smooth curve X , it is possible to associate a positive integer, g , called the genus of X . One can show that given a curve X of genus g , having at least n points with coordinates in $\mathbf{F}_{\mathrm{q}}$, and of an integer a satisfying $0<\mathrm{a}<\mathrm{n}$, then one can construct a $\mathbf{F}_{\mathrm{q}}$ - code, with parameters :

$$
[\mathrm{n} ; \mathrm{k} \geq \mathrm{a}-\mathrm{g}+1 ; \mathrm{d} \geq \mathrm{n}-\mathrm{a}]_{\mathrm{q}} .
$$

If, in addition, $\mathrm{a}>2 \mathrm{~g}-2$, then $\mathrm{k}=\mathrm{a}-\mathrm{g}+1$. For more details, see for example [1]. It is clear that these codes satisfy the following :

Proposition 3: Let $\mathrm{C}=[\mathrm{n} ; \mathrm{k} \geq \mathrm{a}-\mathrm{g}+1 ; \mathrm{d} \geq \mathrm{n}-\mathrm{a}]_{\mathrm{q}}$ be a Goppa code, constructed from a curve $X$ of genus $g$. Then :

$$
R(C)+\delta(C) \geq 1+\frac{1-g}{n}
$$

Remarks: 1) A code C is said to be MDS (Maximum Distance Separable) if its parameters satisfy $\quad R(c)+\delta(c)=1+\frac{1}{n}$. Proposition 3 shows that Goppa codes constructed from curves of genus 0, e.g. from $\mathbf{P}^{1}\left(\mathbf{F}_{\mathrm{q}}\right)$, are MDS.
2) The family of Goppa codes is not particular. In fact, each code can be obtained as a subcode of a Goppa code (see [1]). For example, Michon (see [4]) showed how to obtain BCH codes as Goppa codes. It would be interesting to obtain the Golay code in this way.

Proposition 3 shows the importance of the number $\mathrm{g} / \mathrm{n}$ associated to a curve X : the smaller will be this number, the better will be the parameters of the code so constructed. For $g \in \mathbf{N}$, let $\mathrm{N}_{\mathrm{q}}(\mathrm{g})$ be the maximum number of points of a curve X defined over $\mathbf{F}_{\mathrm{q}}$, of genus g , and let

$$
A(\mathrm{q})=\lim _{\mathrm{g} \varnothing_{+}} \sup _{\mathrm{e}} \frac{\mathrm{~N}_{\mathrm{q}}(\mathrm{~g})}{\mathrm{g}}
$$

The study of $A(q)$ requires number theory and algebraic geometry. The following theorem, and its corollaries, precise the impact of this study for coding theory :

Theorem 4. (Tsfasman). The intersection of the line $R+\delta=1-\frac{1}{A(q)}$ with the square $[0,1] \times[0,1]$, is included in the domain of codes $U_{q}$.

See [6] for a proof.

## Corollary 5. If

$$
\frac{1}{\mathrm{~A}(\mathrm{q})}<\log _{\mathrm{q}} \frac{2 \mathrm{q}-1}{\mathrm{q}}
$$

then there exist excellent families of codes defined over $\mathbf{F}_{\mathrm{q}}$.

Corollary 6. For every $\delta \in[0,1]$,

$$
\mathrm{a}_{\mathrm{q}}(\delta) \geq \operatorname{Max}\left(\alpha_{q}(\delta) ; 1-\delta-\mathrm{A}(\mathrm{q})^{-1}\right)
$$

Remark : It is clear that these two corollaries remain true if we replace $A(q)$ by any lower bound $\overline{\mathrm{A}}(\mathrm{q})$ of $\mathrm{A}(\mathrm{q})$.

Corollary 6 is an easy consequence of theorems 2 and 4 . Next, we prove corollary 5 : the Varshamov - Gilbert curve is convex, decreasing, and has as Tangent line of slope - 1 the line $R+\delta=1-\log _{q} \frac{2 q-1}{q}$. Since this line is parallel to the line $R+\delta=1-A(q)^{-1}$, the latter will lie above to the former if and only if $A(q)^{-1}<\log _{q} \frac{2 q-1}{q}$. In this case, the latter cut the Varshamov-Gilbert curve in two distinct points, and the segment of the line $\mathrm{R}+\delta=1-\mathrm{A}(\mathrm{q})^{-1}$ delimited by these two points lies above the Varshamov - Gilbert curve, and is included in $\mathrm{U}_{\mathrm{q}}$ by theorem 4.

So we have to find lower bound of $\mathrm{A}(\mathrm{q})$ as great as possible.

## III. Lower bounds of $\mathbf{A ( q )}$.

1. The first lower bound, obtained in [7] by Tsfasman, Vladut and Zink, was the following : if $q$ is a square, then $\mathrm{A}(\mathrm{q}) \geq \sqrt{ } \mathrm{q}-1$. Ihara proved using Weil's formulae that for all $\mathrm{q}, \mathrm{A}(\mathrm{q}) \leq \sqrt{ } \mathrm{q}-1$. Hence, this can be reformulated as follows :

Theorem 7. If $q$ is a square, then $A(q)=\sqrt{ } q-1$.

One can remark that, for q square, the inequality

$$
A(q)^{-1}=\frac{1}{\sqrt{q-1}}<\log _{q} \frac{2 q-1}{q}
$$

is true if $\mathrm{q} \geq 49$. So, corollary 5 shows the well known :

Corollary 8. If $q$ is a square, $q \geq 49$, then there exist excellent families of codes over $\mathbf{F}_{\mathrm{q}}$.

The proof of theorem 7 is hard. It involves the reduction modulo $q$ of Shimura curves. Unfortunately, these curves are intractable in practice, e.g. they do not permit an effective construction of the excellent families of codes introduced in corollary 8 (see [3] ). We give, in the end of the paper, two constructive lower bounds for $\mathrm{A}(\mathrm{q})$.

## 2. Serre's lower bound.

Theorem 9. (Serre). There exists a constant $\mathrm{c}>0$, such that for all q :

$$
A(q) \geq c \log q .
$$

The key point of theorem 9 is the following :

Lemma 10. Let $\mathbf{I}$ be a prime number, $\mathrm{q} \equiv 1(\bmod \mathbf{I})$. If there exists $A$ and $B$ included in $\mathbf{F}_{\mathrm{q}}$, disjoint, $|\mathrm{A}|=\mathrm{a} \geq 2$, $|\mathrm{B}|=\mathrm{b} \geq 1$, such that :
a) $\mathrm{B}-\mathrm{A} \subset \mathbf{F}_{\mathrm{q}}^{\mathrm{X} \mathbf{I}}=\left\{\mathrm{X}^{\mathbf{I}} ; \mathrm{x} \in \mathbf{F}_{\mathrm{q}}^{\mathrm{X}}\right\}$,
b) $\mathrm{a}+\mathrm{lb}-1 \leq(\mathrm{a}-1)^{2 / 4}$,
c) $(\mathrm{a}, \mathbf{l})=1$,
then :

$$
\mathrm{A}(\mathrm{q}) \geq \frac{2 \mathrm{lb}}{(\mathrm{a}-1)(\mathrm{I}-1)}
$$

The proof of this lemma involves class field theory. More precisely, we search a condition, for a given function field of one variable over $\mathbf{F}_{\mathrm{q}}$ (which is a global field), to have an infinite $\mathbf{l}$-tower of class fields. For more details, see [5]. We will simply show how to deduce theorem 9 from lemma 10.

Lemma 11. Let (S,E) be a graph, $\omega=|\mathrm{S}|$, and let $\mathrm{a}, \mathrm{b}$ and m three positive integers. We suppose that:

1) $\forall y \in S,\left|S^{-1}\{y\}\right|=|\{x \in S ;(x, y) \in E\}| \geq m$.
2) $b\binom{\omega}{a} \leq \omega\binom{m}{a}$.

Then there exist $A, B \subset S,|A|=a,|B|=b$, such that $A x B \subset E$.

Proof : Let $T=\left\{(A, y) \in 2^{S} x S ;|A|=a ; A x\{y\} \subset E\right\}$.
. We consider the surjective map $\psi: T \rightarrow S$, given by : (A,y) $\rightarrow \mathrm{y}$. The first hypothesis shows that $\left|\psi^{-1}\{y\}\right| \geq\binom{ m}{a}$. Since the inverse images of points are disjoint, $|T| \geq|S|\binom{m}{a}=\omega\binom{m}{a}$.
. We next consider the surjective map $\varphi: T \rightarrow\binom{S}{\mathrm{a}}=\{\mathrm{X} \subset \mathrm{S} ;|\mathrm{X}|=\mathrm{a}\}$, given by $:(\mathrm{A}, \mathrm{y}) \rightarrow \mathrm{A}$. Since $I T I \geq \omega\binom{m}{a}$, and since $T$ is the union of inverse images by $\varphi$ of the elements of $\binom{S}{a}$, there exists at least one element $A_{0}$ of $\binom{S}{a}$, such that $\left|\varphi^{-1}\left(A_{0}\right)\right| \geq \frac{\omega\binom{m_{a}}{a}}{\left|\binom{\mathrm{~S}}{\mathrm{a}}\right|} \geq \mathrm{b}$ by 2 ). Now let $\mathrm{B}_{0} \subset \varphi^{-1}\left(\mathrm{~A}_{0}\right),\left|\mathrm{B}_{0}\right|=\mathrm{b}$. The pair $\mathrm{A}_{0}, \mathrm{~B}_{0}$ satisfy the conclusion of lemma 11.

Corollary 12. Let $\mathbf{l}=2$ (resp. 3) if $q$ is odd (resp. even). Let $a(q)$ and $b(q)$ two integer valued functions of q , such that $\mathrm{a}(\mathrm{q}) \sim \mathrm{d}_{1} \log \mathrm{q}, \mathrm{b}(\mathrm{q}) \sim \mathrm{d}_{2} \log ^{2} \mathrm{q} \leq \mathrm{q}^{\varepsilon}$ for q large, where $\mathrm{d}_{1}, \mathrm{~d}_{2}$ and $\varepsilon$ are three real numbers satisfying $\varepsilon+d_{1} \log l<1$. Then there exist, for $q$ large enough, $A$ and $B \subset \mathbf{F}_{q},|A|=a(q),|B|=b(q)$, such that $A-B \subset \mathbf{F}_{q}^{X_{\mathbf{I}}}$.

Proof : This is a consequence of lemma 11 with $\mathrm{S}=\mathbf{F}_{\mathrm{q}}, \mathrm{E}=\left\{(\mathrm{x}, \mathrm{y}) \in \mathbf{F}_{\mathrm{q}}{ }^{2}{ }^{2} ; \mathrm{x}-\mathrm{y} \in \mathbf{F}_{\mathrm{q}}^{\mathrm{X} \mathbf{I}}\right\}$, and $\mathrm{m}=\frac{\mathrm{q}-1}{\mathrm{l}}$. The inequality

$$
\mathrm{b}(\mathrm{q})(\underset{\mathrm{a}(\mathrm{q})}{\mathrm{q}}) \leq \mathrm{q}(\mathrm{~m}(\mathrm{q}))
$$

holds for $q$ sufficiently large if $1-\varepsilon-d_{1} \log \mathbf{l}>0$. One can see that by using Stirling formulae.

Next, theorem 9 is an easy consequence of lemma 10 and corollary 12.

Remarks : 1) If q is odd, $\mathrm{q} \geq 13$, then $\mathrm{A}(\mathrm{q}) \geq \alpha \log \mathrm{q}$, with $\alpha=0,08734 . .>\frac{1}{12}$. If q is even, q $\geq 32$, then $\mathrm{A}(\mathrm{q})>\beta$ logq, with $\beta=0,02727$.. $>\frac{1}{37}$. In order to compute the constant c of
theorem 9, it is enough to minore $\mathrm{A}(3), \mathrm{A}(5), \ldots, \mathrm{A}(11)$, and $\mathrm{A}(2), \mathrm{A}(4), \mathrm{A}(8)$, and $\mathrm{A}(16)$. For example, Serre showed that $A(2)>\frac{8}{39}$.
2) Since

$$
\log _{\mathrm{q}} \frac{2 \mathrm{q}-1}{\mathrm{q}} \sim \frac{\log 2}{\log \mathrm{q}}
$$

the existence of excellent families of codes over $\mathbf{F}_{\mathrm{q}}$ for q large enough would result from corollary 5 and theorem 9 if we could show that $\mathrm{c}>\frac{1}{\log 2}$. Unfortunately, this bound has not been obtened yet.

## 3. The main theorems.

a) The first is the following :

Theorem 13. Let $\mathbf{I}$ be a prime number, and suppose that $q>4 \mathbf{I}+1$. Let $k$ be a positive integer. If $q$ is a primitive $k$-root of the unity in $\mathbf{F}_{\mathbf{l}}$, then :

$$
A\left(q^{\mathbf{l}}\right) \geq \frac{\sqrt{ } \mathbf{l}-2 \mathbf{l}}{\mathbf{l}-1} \quad \text { if } k=1(\text { e.g. if } q \equiv 1(\bmod \mathbf{l}))
$$

and

$$
A\left(q^{k}\right) \geq \frac{\sqrt{ } 1-2 l}{l-1} \quad \text { if } k \geq 2
$$

For example : 1$)$ If $q \equiv 1(\bmod 3)$, or if $q \equiv 2$ or $4(\bmod 7)$, and if $q>13$, then :

$$
A\left(q^{3}\right) \geq \frac{\sqrt{3}}{2} \sqrt{q-1}-3
$$

2) If $\mathrm{q} \equiv 1(\bmod 5)$, and if $q>21$, then :

$$
A\left(q^{5}\right) \geq \frac{\sqrt{ } 5}{4} \sqrt{q-1}-\frac{5}{2}
$$

Theorem 13 will be a consequence of the following lemma :

Lemma $\mathbf{1 4}$ : If Q is a power of $\mathrm{q}, \mathrm{q}>4 \mathbf{I}+1, \mathrm{Q} \equiv 1(\bmod \mathbf{I})$, and if all elements of $\mathbf{F}_{\mathrm{q}}$ are -power in $\mathbf{F}_{\mathrm{Q}}$, then :

$$
\mathrm{A}(\mathrm{Q}) \geq \frac{\sqrt{ } \mathbf{l}-2 \mathbf{l}}{\mathbf{l}-1}
$$

This lemma imply theorem 13 thank to the following remarks :
-If $\mathrm{q} \equiv 1(\bmod \mathbf{l})$, then all elements of $\mathbf{F}_{\mathrm{q}}$ is a $\mathbf{l}$-power in $\mathbf{F}_{\mathrm{q}} \mathbf{I}$.
-If $(\mathbf{l}, \mathrm{q}-1)=1$, then all elements of $\mathbf{F}_{\mathrm{q}}$ is a $\mathbf{l}$-power in $\mathbf{F}_{\mathrm{q}}$, hence in $\mathbf{F}_{\mathrm{q}}$.
Then one can apply lemma 10 , with $Q=q^{\mathbf{l}}$ (resp. $\left.q^{k}\right)$, since in the first case $q^{\mathbf{l}} \equiv 1(\bmod \mathbf{I})$, and in the second case $\mathrm{q}^{\mathrm{k}} \equiv 1(\bmod \mathbf{1})$, which is a fundamental hypothesis of lemma 14.

We have now to give a demonstration of lemma 14. we choose as a pair A,B of lemma 10 a partition of $\mathbf{F}_{\mathrm{q}}$.The condition b ) of lemma 10 , together with $\mathrm{a}+\mathrm{b}=\mathrm{q}$, enable us to calculate a and $b$ as better as possible. Taking few precautions so that $(a, l)=1$, the lower bound of lemma 10 gives the lower bound of lemma 14.
b) Finally, theorem 13 , together with corollary 5 , shows that :

Theorem 15. Under the assumptions and notations of theorem 13, if

$$
\frac{\mathbf{l}-1}{\sqrt{\mathbf{l}-2 \mathbf{l}}<\log _{q} \mathbf{l} \frac{2 \mathrm{q}^{\mathbf{l}}-1}{\mathrm{q}^{\mathbf{l}}}, ~, ~, ~}
$$

(resp. if

$$
\left.\frac{\mathbf{l}-1}{\sqrt{\mathbf{l}-2 \mathbf{l}}}<\log _{q^{k}} \frac{2 \mathrm{q}^{\mathrm{k}}-1}{\mathrm{q}^{\mathrm{k}}}\right)
$$

then there exist excellent families of codes over $\mathbf{F}_{\mathrm{q}} \mathbf{I}\left(\right.$ resp. $\mathbf{F}_{\mathrm{q}}$ ).

For example, our construction shows the existence of excellent families of $\mathbf{F}_{\mathrm{q}} \mathbf{1}$ - codes in the following cases:

1) $\mathbf{l}=2, q \geq 191$ and $q$ odd, which is not as good as the result of corollary 8 .
2) $\mathbf{I}=3, q \geq 1657$, and $q \equiv 1(\bmod 3)$ or $q \equiv 2$ or $4(\bmod 7)$;
3) $\mathbf{I}=5, q \geq 16981$, and $q \equiv 1(\bmod 5)$.
